#### Abstract

This research developed an economic order quantity model for non-instantaneous deteriorating items with two-phase demand rates, linear holding cost, constant partial backlogging rate and two-level pricing strategies under trade credit policy. It is assumed that the holding cost is linear time-dependent, the unit selling price before deterioration sets in is greater than that after deterioration sets and the demand rate before deterioration sets in is considered as continuous time-dependent quadratic, after which it is considered as constant up to when the inventory is completely exhausted. Shortages are allowed and partially backlogged. The purpose of the model is to determine the optimal time with positive inventory, cycle length and order quantity such that the total profit of the inventory system has a maximum value. The necessary and sufficient conditions for the existence and uniqueness of the optimal solutions have been established. Some numerical examples have been given to illustrate the theoretical result of the model. Sensitivity analysis of some model parameters on the decision variables has been carried out and suggestions towards maximising the total profit were also given., it is seen that the higher the rate of deterioration $(\theta)$, the lower the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length $\left(T^{*}\right)$, order quantity $\left(E O Q^{*}\right)$ and the total profit $T P\left(T^{*}\right)$ and vice versa. This implies that the retailer needs to take all the necessary measures to avoid or reduce deterioration to maximise higher profit. Based on the results application of the model led to an increase in revenue.

## INTRODUCTION

Deterioration refers to damage, spoilage, dryness, vaporisation, etc., that result in a decrease in the usefulness of the commodity. The assumption in the classical EOQ models that items in the stock preserve their original characteristics/conditions forever may not always apply to most physical goods (i.e. which deteriorate with time due to obsolesce, loss of utility, decay, damage, degradation and decrease in their usefulness). Deterioration of goods is an unavoidable phenomenon, and its study plays an essential role in any business organisation's smooth and efficient running. Researchers such as Geetha and Udayakumar (2016), Babangida and Baraya (2020) developed an inventory model with non-instantaneous deterioration under various assumptions.

The classical EOQ model assumes that customers must pay for the goods purchased as soon as it is received. However, in a real market situation, the supplier allows the
customers to pay their debt within a specific period, known as the trade credit period. The retailer can accumulate revenues by selling items and by earning interest. The concept of trade credit in the inventory literature was first introduced by Haley and Higgins (1973). Goyal (1985) was the first to propose an EOQ model for non-decaying items with a constant demand rate under permissible delay in payments and assumed that the unit purchasing cost and selling price per unit are the same. Later, Aggarwal and Jaggi (1995) extended Goyal's (1985) model to develop an inventory model for deteriorating items with a constant demand rate under permissible payment delays. Soni and Chauhan (2018) investigated a joint pricing, inventory, and preservation decision-making problem for deteriorating items subject to stochastic demand and promotional effort. The generalised price-dependent stochastic demand, timeproportional deterioration, and partial backlogging rates are used to model the inventory system. The objective is

to find the optimal pricing, replenishment, and preservation technology investment strategies while maximising the total profit per unit of time.
Mohsen et al. (2018) proposed an economic order quantity model for non-instantaneous deteriorating items under a hybrid payment schedule. This payment schedule comprises a multiple advanced payment scheme and a delayed payment plan. Here, a retailer must prepay a portion of the purchasing cost to his supplier during the order delivery lead time, in several instalments.
Under a trade credit policy, Umakanta et al. (2018) developed an inventory model for deteriorating items with a controllable deterioration rate (using preservation technology). As in practical scenarios, the demand for an item is directly associated with its selling price. Keeping this in mind, it is assumed to be a price-dependent demand.
Bhaula et al. (2019) derived an optimal ordering policy for non-instantaneously deteriorating items under successive price discounts with payment delays. Here, successive price discounts are a strategy to sell almost all the items before decomposition. The cause of implementing this concept in the model is that about $25 \%$ of vegetables and fruits in India decayed before selling due to a lack of facilities and awareness of business strategies, although poverty is a vital factor. Thus, we propose to offer successive price discounts of $20 \%$ and $40 \%$ after selling the stock up to $50 \%$ and $90 \%$, respectively, to raise the customer's inflow and rotate the cycle early to avoid more deterioration.
Later researchers such as Babangida and Baraya [(2018), (2019), (2022), (2021a)], Tripathy and Sharma (2022), Sheng and Jinn (2014), Majunder and Kumar (2019) and so on develop inventory models with trade credit policy under various assumptions.
In the classical inventory model, shortages are not allowed. However, sometimes, customers' demands cannot be fulfilled by the supplier from the current stocks. This situation is known as stock out or shortage condition. However, when all the customers are willing to wait for the backorder, the situation is referred to as complete backlogging. Researchers such as Mahato and Mahata (2023), Tiwari et al. (2022), Choudhury et al. (2013), Babangida and Baraya [(2019), (2020)] and so on developed inventory models with complete backlogging under various assumptions.
Moreover, when certain customers constantly wait for the supplier to supply the goods, the situation is called constant partial backlogging. For example, the customers who constantly wait for the backorder might be the supplier's close friends and relatives. Many researchers, such as Baraya and Sani (2013), Bello and Baraya (2018), Babangida and Baraya (2021b), and so on, developed inventory models with constant partial backlogging rates under various assumptions. Furthermore, there are scenarios whereby the customers wait for the backorder based on the time taken before the next replenishment, known as the time-dependent partial backlogging rate. Researchers such as Babangida and Baraya (2022), Geetha and Uthayakumar (2010), Babangida et al. (2023),

Umakanta and Chaitanya (2012), Sarkar and Sarkar (2013) developed an inventory model with time-dependent partial backlogging under various assumption.
Babangida and Baraya (2021a) developed an EOQ model for non-instantaneous deteriorating items with two-phase demand rates and two-level pricing strategies under trade credit policy. It is assumed that the unit-selling price before deterioration is greater than after deterioration. In addition, the demand rate before deterioration sets in is assumed to be continuous time-dependent quadratic and is considered constant after deterioration sets in. Holding cost is considered as constant and shortages are not allowed. However, in real-life situations, the holding cost of many items may be dynamic as there is a change in the time value of money and price index. Therefore, the model is extended by considering linear holding cost and constant partial backlogging rate.
The purpose of the model is to determine the optimal time with positive inventory, cycle length and order quantity such that the total profit of the inventory system has a maximum value.
Moreover, if the model is accepted, it will help retailers to increase cash flow, encourage sales, reduce the cost of holding stock, attract new customers, decrease the levels of inventory loss due to deterioration, boost market share or retain customers, increase the cycle length, spread the ordering cost over a long period, reduce the total variable cost of the inventory and generate more revenue.
This paper model considers an EOQ model for noninstantaneous deteriorating items with two phase demand rate, two level pricing strategies, linear holding cost and constant partial backlogging rate under trade credit policy. The demand rate before deterioration sets in is assumed to be time-dependent quadratic, which is considered constant after deterioration sets in. It is also assumed that the unit selling price is different before and after deterioration sets in. The holding cost is assumed to be linear time-dependent. Shortages are allowed with a constant partial backlogging rate.

## NOTATIONS AND ASSUMPTIONS

## Notation:

The inventory system is developed using the following notations.

## A The fixed ordering cost per order

$C$ The purchasing cost per unit time
$S_{1} \quad$ Unit selling price during the interval $\left[0, t_{d}\right]$
$S_{2} \quad$ Unit selling price during the interval $\left[t_{d}, T\right]$, where $S_{1}>S_{2}>C$
$C_{b} \quad$ Shortage cost per unit time
$I_{C} \quad$ The interest charged in stock by the supplier
$I_{e} \quad$ The interest earned
$M$ The trade credit period (in year for settling account)
$\theta$ The constant deterioration rate function
$t_{d}$ The length of time in which the product exhibit more deterioration
$t_{1}$ Length of time in which the inventory has no shortage
$T$ The length of replenishment cycle time
$Q_{m} \quad$ The maximum inventory level
$B_{m} \quad$ The backorder level during the shortage period
$Q \quad$ The order quantity during the cycle length i.e. $Q=$ $Q_{m}+B_{m}$
$C_{\pi}$ Unit cost of lost sales per unit
$\delta$ Backlogging parameter

## Assumptions

In addition to assumptions 8 and 9, which are not considered in Babangida and Baraya (2021a), this model develops under the following assumptions, which have been adapted from the aforementioned research.

1. The replenishment rate is infinite, i.e., the replenishment rate is instantaneous, and the lead time is zero.
2. During the fixed period, $t_{d}$, there is no deterioration, and at the end of this period, the inventory item deteriorates at the rate $\theta$.
3. There is no replacement or repair for deteriorating items.
4. The demand rate before deterioration begins is assumed to be continuous time-dependent quadratic and is given by
$a+b t+c t^{2}$, where $a \geq 0, b \neq 0, c \neq 0 c \neq 0$. Here $a$ is the initial demand rate, $b$ is the rate at which the demand rate changes and $c$ is the accelerated change in the demand rate.
5. The demand rate after deterioration sets in is assumed to be constant and is given by $d, d>0$.
6. During the trade credit period $M(0<M<1)$, the account is not settled; generated sales revenue is deposited in an interest-bearing account. At the end of the period, the retailer pays off all units bought and starts to pay the capital opportunity cost for the items in stock. No interest is earned after the trade credit period.
7. The unit selling price is not the same as the unit purchasing cost. It is assumed that the unit selling price before deterioration sets in is greater than that after deterioration sets in $\left(S_{1}>S_{2}>C\right)$.
8. Shortages are allowed and partially backlogged.
9. Holding cost $C_{1}(t)$ per unit time is linear timedependent and is assumed to be $C_{1}(t)=h_{1}+h_{2} t$; where $h_{1}>0$ and $h_{2}>0$.

## FORMULATION OF THE MODEL

$Q_{m}$ units of items are ordered at the beginning of the cycle (i.e., at time $t=0$ ). During the interval $\left[0, t_{d}\right]$, the inventory level is depleting gradually due to market demand only and the demand rate is assumed to be time dependent quadratic. At time interval $\left[t_{d}, t_{1}\right]$, the inventory level is depleting due to the combined effects of customer demand and deterioration, and the demand rate reduces to $d$. At time $t=t_{1}$, the inventory level depletes to zero. Shortages occur at the time interval $\left[t_{1}, T\right]$ and partially backlogged at the rate $\delta$, the behaviour of the inventory system is described in Figure 1 below:

Figure 1: Graphical representation of the inventory system

During the time interval $\left[0, t_{d}\right]$, the change of inventory at any time $t$ is represented by the following differential equations
$\frac{d I_{1}(t)}{d t}=-\left(a+b t+c t^{2}\right)$,

$$
\begin{equation*}
0 \leq t \leq t_{d} \tag{1}
\end{equation*}
$$

with boundary conditions $I_{1}(0)=Q_{m}$ and $I_{1}\left(t_{d}\right)=Q_{d}$.
Graphical representation of the inventory system
$\frac{d I_{2}(t)}{d t}+\theta I_{2}(t)=-d, \quad t_{d} \leq t \leq t_{1}$
With boundary condition $I_{2}\left(t_{1}\right)=0$ at $t=t_{1}$ and $I_{2}\left(t_{d}\right)=Q_{d}$ at $t=t_{d}$
$\frac{d I_{3}(t)}{d t}=-\delta d$,

$$
\begin{equation*}
t_{1} \leq t \leq T \tag{3}
\end{equation*}
$$

With the boundary condition $I_{3}\left(t_{1}\right)=0$ at $t=t_{1}$ and $I_{3}\left(t_{1}\right)=0$ at $t=t_{1}$.
The solution of equations (1), (2) and (3) are respectively given by
$I_{1}(t)=a\left(t_{d}-t\right)+\frac{b}{2}\left(t_{d}^{2}-t^{2}\right)+\frac{c}{3}\left(t_{d}^{3}-t^{3}\right)+Q_{d} \quad 0 \leq t \leq t_{d}$
$I_{2}(t)=\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t\right)}-1\right)$,
$t_{d} \leq t \leq t_{1}$
$I_{3}(t)=\delta d\left(t_{1}-t\right)$
$t_{1} \leq t \leq T$
From Figure 1, using the condition $I_{1}(0)=Q_{m}$ in equation (4), the maximum stock level is given by
$Q_{m}=\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)+\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)$
Similarly, the value of $Q_{d}$ can be derived at $t=t_{d}$, then it follows from equation (5) that
$Q_{d}=\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)$
The maximum backordered inventory $B_{m}$ is obtained at $t=T$, and then from equation (6), it follows that
$B_{m}=d \delta\left(T-t_{1}\right)$
Therefore, the order size $Q$ during the period $[0, T]$ is obtained as the sum of maximum inventory level $Q_{m}$ and maximum backordered inventory $B_{m}$
$Q=\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)+\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)+\delta d\left(T-t_{1}\right)$
(i) The total demand during the period $\left[t_{d}, t_{1}\right]$ is given by
$D_{M}=\int_{t_{d}}^{t_{1}} d d t=d\left(t_{1}-t_{d}\right)$
(ii) The total number of deteriorated items per cycle is given by
$D_{P}=\frac{d}{\theta}\left[e^{\theta\left(t_{1}-t_{d}\right)}-1-\theta\left(t_{1}-t_{d}\right)\right]$
(iii) Total number of items sold

$$
\begin{equation*}
S N=Q-D_{P}=\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)+d\left(t_{1}-t_{d}\right)+\delta d\left(T-t_{1}\right) \tag{13}
\end{equation*}
$$

(iv) Sale revenue (SR)
$S R=S_{1}\left[\int_{0}^{t_{d}}\left(a+b t+c t^{2}\right) d t\right]+S_{2}\left[\int_{t_{d}}^{t_{1}} d d t+\int_{t_{1}}^{T} \delta d d t\right]$
$=S_{1}\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)+S_{2} d\left(t_{1}-t_{d}\right)+S_{2} \delta d\left(T-t_{1}\right)$
(v) Purchasing cost (PC)

$$
\begin{equation*}
P C=C Q=C\left[\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)+\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)+\delta d\left(T-t_{1}\right)\right] \tag{15}
\end{equation*}
$$

(iv) The fixed ordering cost per order is given by $A$
(v) The inventory holding cost for the entire cycle is given by
$C_{H}=\int_{0}^{t_{d}}\left(h_{1}+h_{2} t\right) I_{1}(t) d t+\int_{t_{d}}^{t_{1}}\left(h_{1}+h_{2} t\right) I_{2}(t) d t$
Substituting equations (4) and (5) into equation (16)

$$
\begin{align*}
& C_{H}=h_{1}\left[\frac{d t_{d}}{\theta} e^{\theta\left(t_{1}-t_{d}\right)}+\frac{a}{2} t_{d}^{2}+\frac{b}{3} t_{d}^{3}+\frac{c}{4} t_{d}^{4}+\frac{d}{\theta^{2}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d}{\theta^{2}}-\frac{d t_{1}}{\theta}\right] \\
&+h_{2}\left[\frac{d t_{d}^{2}}{2 \theta} e^{\theta\left(t_{1}-t_{d}\right)}+\frac{a}{6} t_{d}^{3}+\frac{b}{8} t_{d}^{4}+\frac{c}{10} t_{d}^{5}+\frac{d t_{d}}{\theta^{2}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d t_{1}}{\theta^{2}}-\frac{d}{\theta^{3}}+\frac{d}{\theta^{3}} e^{\theta\left(t_{1}-t_{d}\right)}\right. \\
&\left.-\frac{d t_{1}^{2}}{2 \theta}\right] \tag{17}
\end{align*}
$$

(vi) The backordered cost per cycle is given by
$S C=C_{b} \int_{t_{1}}^{T}-I_{3}(t) d t$

$$
\begin{equation*}
=\frac{C_{b} \delta d}{2}\left(T-t_{1}\right)^{2} \tag{18}
\end{equation*}
$$

(vii) The opportunity cost per cycle due to lost sales is given by
$L C=C_{\pi} \int_{t_{1}}^{T} d(1-\delta) d t=C_{\pi} d(1-\delta)\left(T-t_{1}\right)$
(vii) The total profit per unit time for a replenishment cycle (denoted by $\operatorname{TP}\left(t_{1}, T\right)$ is given by
$T P\left(t_{1}, T\right)=\left\{\begin{array}{cr}T P_{1}\left(t_{1}, T\right) & 0<M \leq t_{d} \\ T P_{2}\left(t_{1}, T\right) & t_{d}<M \leq t_{1} \\ T P_{3}\left(t_{1}, T\right) & M>t_{1}\end{array}\right.$
where $T P_{1}\left(t_{1}, T\right), T P_{2}\left(t_{1}, T\right)$, and $T P_{3}\left(t_{1}, T\right)$ are discussed for three different cases follows.
Case 1: $\left(0<M \leq \boldsymbol{t}_{\boldsymbol{d}}\right)$
The interest payable
This is the period before deterioration sets in, and payment for goods is settled with the capital opportunity cost rate $I_{c}$ for the items in stock. Therefore, the interest payable is given below.

$$
\begin{align*}
I_{P 1}=C I_{c}\left[\int_{M}^{t_{d}} I_{1}\right. & \left.(t) d t+\int_{t_{d}}^{t_{1}} I_{2}(t) d t\right] \\
& =C I_{c}\left[\frac{d\left(t_{d}-M\right)}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)+\frac{a}{2}\left(t_{d}-M\right)^{2}+\frac{b}{6}\left(2 t_{d}+M\right)\left(t_{d}-M\right)^{2}\right. \\
& \left.+\frac{c}{12}\left(3 t_{d}^{2}+2 t_{d} M+M^{2}\right)\left(t_{d}-M\right)^{2}+\frac{d}{\theta^{2}}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1-\theta\left(t_{1}-t_{d}\right)\right)\right] \tag{21}
\end{align*}
$$

## The interest earned

In this case, the retailer can earn interest on revenue generated from the sales up to the trade credit period $M$. Although the retailer has to settle the accounts at period $M$, for that, he has to arrange money at some specified rate of interest to get his remaining stocks financed for the period $M$ tot $t_{d}$. The interest earned is
$I_{E 1}=S_{1} I_{e}\left[\int_{0}^{M}\left(a+b t+c t^{2}\right) t d t\right]$
$=S_{1} I_{e}\left(a \frac{M^{2}}{2}+b \frac{M^{3}}{3}+c \frac{M^{4}}{4}\right)$
The total profit per unit time for case $1\left(0<M \leq t_{d}\right)$ is
$T P_{1}\left(t_{1}, T\right)=\frac{1}{T}\{$ Sales Revenue - Purchasing cost - Ordering cost - inventory holding cost - backordered cost - lost sales cost- interest payable during the permissible delay period + interest earned during the cycle $\}$

$$
\begin{align*}
=\frac{1}{T}\left\{\left(S_{1}-C\right)( \right. & \left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)+S_{2} d\left(t_{1}-t_{d}\right)+\left(S_{2}-C\right) \delta d\left(T-t_{1}\right)-C\left[\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)\right]-A \\
& -h_{1}\left[\frac{d t_{d}}{\theta} e^{\theta\left(t_{1}-t_{d}\right)}+\frac{a}{2} t_{d}^{2}+\frac{b}{3} t_{d}^{3}+\frac{c}{4} t_{d}^{4}+\frac{d}{\theta^{2}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d}{\theta^{2}}-\frac{d t_{1}}{\theta}\right] \\
& -h_{2}\left[\frac{d t_{d}^{2}}{2 \theta} e^{\theta\left(t_{1}-t_{d}\right)}+\frac{a}{6} t_{d}^{3}+\frac{b}{8} t_{d}^{4}+\frac{c}{10} t_{d}^{5}+\frac{d t_{d}}{\theta^{2}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d t_{1}}{\theta^{2}}-\frac{d}{\theta^{3}}+\frac{d}{\theta^{3}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d t_{1}^{2}}{2 \theta}\right] \\
& -\frac{C_{b} \delta d}{2}\left(T-t_{1}\right)^{2}-C_{\pi} d(1-\delta)\left(T-t_{1}\right) \\
& -c I_{c}\left[\frac{d\left(t_{d}-M\right)}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)+\frac{a}{2}\left(t_{d}-M\right)^{2}+\frac{b}{6}\left(2 t_{d}+M\right)\left(t_{d}-M\right)^{2}\right. \\
& \left.+\frac{c}{12}\left(3 t_{d}^{2}+2 t_{d} M+M^{2}\right)\left(t_{d}-M\right)^{2}+\frac{d}{\theta^{2}}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1-\theta\left(t_{1}-t_{d}\right)\right)\right] \\
& \left.+S_{1} I_{e}\left(a \frac{M^{2}}{2}+b \frac{M^{3}}{3}+c \frac{M^{4}}{4}\right)\right\} \tag{23}
\end{align*}
$$

Case 2: $\left(\boldsymbol{t}_{\boldsymbol{d}}<M \leq \boldsymbol{t}_{1}\right)$

## The interest payable

This is when the endpoint of the credit period is greater than the period with no deterioration but shorter than or equal to the length of the period with positive inventory stock of the items. The interest payable is
$I_{P 2}=c I_{c}\left[\int_{M}^{t_{1}} I_{2}(t) d t\right]$
$=c I_{c}\left[\frac{d}{\theta^{2}}\left(e^{\theta\left(t_{1}-M\right)}-1-\theta\left(t_{1}-M\right)\right)\right]$

## The interest earned

In this case, the retailer can earn interest on revenue generated from the sales up to the trade credit period $M$. Although the retailer has to settle the accounts at period $M$, for that, he has to arrange money at some specified rate of interest in order to get his remaining stocks financed for the period $M$ to $t_{1}$. The interest earned is
$I_{E 2}=S_{1} I_{e}\left[\int_{0}^{t_{d}}\left(a+b t+c t^{2}\right) t d t\right]+S_{2} I_{e}\left[\int_{t_{d}}^{M} d t d t\right]$
$=S_{1} I_{e}\left(a \frac{t_{d}^{2}}{2}+b \frac{t_{d}^{3}}{3}+c \frac{t_{d}^{4}}{4}\right)+S_{2} I_{e}\left(\frac{d M^{2}}{2}-\frac{d t_{d}^{2}}{2}\right)$
The total profit per unit time for case $2\left(t_{d}<M \leq t_{1}\right)$ is
$T P_{2}\left(t_{1}, T\right)=\frac{1}{T}\{$ Sales Revenue - Purchasing cost - Ordering cost - inventory holding cost - backordered cost - lost sales cost- interest payable during the permissible delay period + interest earned during the cycle $\}$

$$
\begin{align*}
=\frac{1}{T}\left\{\left(S_{1}-C\right)( \right. & \left.a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)+S_{2} d\left(t_{1}-t_{d}\right)+\left(S_{2}-C\right) \delta d\left(T-t_{1}\right)-C\left[\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)\right]-A \\
& -h_{1}\left[\frac{d t_{d}}{\theta} e^{\theta\left(t_{1}-t_{d}\right)}+\frac{a}{2} t_{d}^{2}+\frac{b}{3} t_{d}^{3}+\frac{c}{4} t_{d}^{4}+\frac{d}{\theta^{2}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d}{\theta^{2}}-\frac{d t_{1}}{\theta}\right] \\
& -h_{2}\left[\frac{d t_{d}^{2}}{2 \theta} e^{\theta\left(t_{1}-t_{d}\right)}+\frac{a}{6} t_{d}^{3}+\frac{b}{8} t_{d}^{4}+\frac{c}{10} t_{d}^{5}+\frac{d t_{d}}{\theta^{2}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d t_{1}}{\theta^{2}}-\frac{d}{\theta^{3}}+\frac{d}{\theta^{3}} e^{\theta\left(t_{1}-t_{d}\right)}-\frac{d t_{1}^{2}}{2 \theta}\right] \\
& -\frac{C_{b} \delta d}{2}\left(T-t_{1}\right)^{2}-C_{\pi} d(1-\delta)\left(T-t_{1}\right)-c I_{c}\left[\frac{d}{\theta^{2}}\left(e^{\theta\left(t_{1}-M\right)}-1-\theta\left(t_{1}-M\right)\right)\right] \\
& \left.+S_{1} I_{e}\left(a \frac{t_{d}^{2}}{2}+b \frac{t_{d}^{3}}{3}+c \frac{t_{d}^{4}}{4}\right)+S_{2} I_{e}\left(\frac{d M^{2}}{2}-\frac{d t_{d}^{2}}{2}\right)\right\} \tag{26}
\end{align*}
$$

Case 3: $\left(M>t_{1}\right)$

## The interest payable

In this case, the period of delay in payment is greater than period with positive inventory. In this case the retailer pays no interest. Therefore, $I_{P 3}=0$.

## The interest earned

In this case, the period of delay in payment $(M)$ is greater than period with positive inventory $\left(t_{1}\right)$. In this case the retailer earns interest on the sales revenue up to the permissible delay period and no interest is payable during the period for the item kept in stock. Interest earned for the time period $[0, T]$
$I_{E 3}=S_{1} I_{e}\left[\int_{0}^{t_{d}}\left(a+b t+c t^{2}\right) t d t+\left(M-t_{1}\right) \int_{0}^{t_{d}}\left(a+b t+c t^{2}\right) d t\right]+S_{2} I_{e}\left[\int_{t_{d}}^{t_{1}} d t d t+\left(M-t_{1}\right) \int_{t_{d}}^{t_{1}} d d t\right]$
$=S_{1} I_{e}\left[\left(a \frac{t_{d}^{2}}{2}+b \frac{t_{d}^{3}}{3}+c \frac{t_{d}^{4}}{4}\right)+\left(M-t_{1}\right)\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)\right]+S_{2} I_{e}\left[-\frac{d}{2}\left(t_{1}-t_{d}\right)^{2}+M d\left(t_{1}-t_{d}\right)\right]$
The total profit per unit time for case $3\left(M>t_{1}\right)$ is
$T P_{3}\left(t_{1}, T\right)=\frac{1}{T}\{$ Sales Revenue - Purchasing cost - Ordering cost - inventory holding cost - backordered cost - lost sales cost + interest earned during the cycle $\}$

$$
\begin{align*}
=\frac{1}{T}\left\{\left(S_{1}-C\right)( \right. & \left.a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)+S_{2} d\left(t_{1}-t_{d}\right)+\left(S_{2}-C\right) \delta d\left(T-t_{1}\right)-C\left[\frac{d}{\theta}\left(e^{\theta\left(t_{1}-t_{d}\right)}-1\right)\right]-A \\

$$

OPTIMAL DECISION
This section determines the optimal ordering policies that maximise the total profit per unit time. The necessary and sufficient conditions for the existence and uniqueness of optimal solutions have been established. The necessary conditions for the total profit per unit time $T P_{i}\left(t_{1}, T\right)$ to be maximum are $\frac{\partial T P_{i}\left(t_{1}, T\right)}{\partial t_{1}}=0$ and $\frac{\partial T P_{i}\left(t_{1}, T\right)}{\partial T}=0$ for $i=1,2,3$. The value of $\left(t_{1}, T\right)$ obtained from $\frac{\partial T P_{i}\left(t_{1}, T\right)}{\partial t_{1}}=0$ and $\frac{\partial T P_{i}\left(t_{1}, T\right)}{\partial T}=0$ and for which the sufficient condition $\left\{\left(\frac{\partial^{2} T P_{i}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right)\left(\frac{\partial^{2} T P_{i}\left(t_{1}, T\right)}{\partial T^{2}}\right)-\left(\frac{\partial^{2} T P_{i}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\right)^{2}\right\}>0$ is satisfied gives a maximum value for the total profit per unit time $T P_{i}\left(t_{1}, T\right)$.
For case $1\left(0<M \leq t_{d}\right)$
The necessary condition for the total profit $T P_{1}\left(t_{1}, T\right)$ in equation (29) to be the maximum are $\frac{\partial T P_{1}\left(t_{1}, T\right)}{\partial t_{1}}=0$ and $\frac{\partial T P_{1}\left(t_{1}, T\right)}{\partial T}=0$, which give
$\frac{\partial T P_{1}\left(t_{1}, T\right)}{\partial t_{1}}=\frac{d}{T}\left\{-X_{1} t_{1}+Y_{1}+C_{b} \delta T\right\}$
Setting $\frac{\partial T P_{1}\left(t_{1}, T\right)}{\partial t_{1}}=0$ gives
$\left\{-X_{1} t_{1}+Y_{1}+C_{b} \delta T\right\}=0$
and
$T=\frac{1}{C_{b} \delta}\left(X_{1} t_{1}-Y_{1}\right)$
Since $\left(t_{d}-M\right) \geq 0,\left(t_{1}-t_{d}\right)>0, t_{1}-M>0$
It should be noted that

$$
\begin{aligned}
\left(X_{1} t_{1}-Y_{1}\right)= & {\left[\left(C-S_{2}\right)(1-\delta)+h_{1}\left(t_{d} \theta\left(t_{1}-t_{d}\right)+t_{1}\right)+h_{2}\left(t_{1}-\frac{t_{d}}{2}\right) t_{d}+\frac{h_{2} t_{d} \theta}{2}\left(t_{1}-t_{d}\right) t_{d}+C \theta\left(t_{1}-t_{d}\right)\right.} \\
& \left.+C_{\pi}(\delta-1)+C_{b} \delta t_{1}+c I_{c}\left(\left(t_{1}-M\right)+\theta\left(t_{d}-M\right)\left(t_{1}-t_{d}\right)\right)\right]>0
\end{aligned}
$$

Provided

$$
\begin{gathered}
{\left[C+S_{2} \delta+h_{1}\left(t_{d} \theta\left(t_{1}-t_{d}\right)+t_{1}\right)+h_{2}\left(t_{1}-\frac{t_{d}}{2}\right) t_{d}+\frac{h_{2} t_{d} \theta}{2}\left(t_{1}-t_{d}\right) t_{d}+C \theta\left(t_{1}-t_{d}\right)+C_{\pi} \delta+C_{b} \delta t_{1}\right.} \\
\left.+c I_{c}\left(\left(t_{1}-M\right)+\theta\left(t_{d}-M\right)\left(t_{1}-t_{d}\right)\right)\right]>\left(S_{2}+C \delta+C_{\pi}\right)
\end{gathered}
$$

Similarly,
$\frac{\partial T P_{1}\left(t_{1}, T\right)}{\partial T}=-\frac{d}{T^{2}}\left\{-\frac{1}{2} X_{1} t_{1}^{2}+Y_{1} t_{1}-W_{1}+\frac{C_{b} \delta T^{2}}{2}\right\}$
Setting $\frac{\partial T P_{1}\left(t_{1}, T\right)}{\partial T}=0$ to obtain
$-\frac{d}{T^{2}}\left\{-\frac{1}{2} X_{1} t_{1}^{2}+Y_{1} t_{1}-W_{1}+\frac{C_{b} \delta T^{2}}{2}\right\}=0$
Substituting $T$ from equation (33) into equation (35) yields
$\left\{X_{1}\left(C_{b} \delta-X_{1}\right) t_{1}^{2}-2 Y_{1}\left(C_{b} \delta-X_{1}\right) t_{1}-\left(Y_{1}^{2}-2 C_{b} \delta W_{1}\right)\right\}=0$
Let $\Delta_{1}=X_{1}\left(C_{b} \delta-X_{1}\right) t_{d}^{2}-2 Y_{1}\left(C_{b} \delta-X_{1}\right) t_{d}-\left(Y_{1}^{2}-2 C_{b} \delta W_{1}\right)$, then the following result is obtained.

## Lemma 1

(i)If $\Delta_{1} \geq 0$, then the solution of $t_{1} \in\left[t_{d}, \infty\right)$ (say $t_{11}^{*}$ ) which satisfies equation (36) not only exists but also is unique.

See the proof in Appendix 1a
(ii)If $\Delta_{1}<0$, then the solution of $t_{1} \in\left[t_{d}, \infty\right)$ which satisfies equation (36) does not exist.

See the proof in Appendix 1b
Therefore, the value of $t_{1}$ (denoted by $t_{11}^{*}$ ) can be found from equation (36) and is given by
$t_{11}^{*}=\frac{Y_{1}}{X_{1}}+\frac{1}{X_{1}} \sqrt{\frac{\left(2 X_{1} W_{1}-Y_{1}^{2}\right) C_{b} \delta}{\left(X_{1}-C_{b} \delta\right)}}$
Once the value of $t_{11}^{*}$ is obtained, then the value of $T$ (denoted by $T_{1}^{*}$ ) can be found from (33) and is given by
$T_{1}^{*}=\frac{1}{C_{b} \delta}\left(X_{1} t_{11}^{*}-Y_{1}\right)$
Equations (37) and (38) give the optimal values of $t_{11}^{*}$ and $T_{1}^{*}$ for the profit function in equation (29) only if $Y_{1}$ satisfies the inequality given in equation (39)
$2 X_{1} W_{1}>Y_{1}^{2}$
Theorem 1
(i)If $\Delta_{1} \geq 0$, then the total profit $T P_{1}\left(t_{1}, T\right)$ is concave and reaches its global maximum at the point $\left(t_{11}^{*}, T_{1}^{*}\right)$, where $\left(t_{11}^{*}, T_{1}^{*}\right)$ is the point which satisfies equations (36) and (32), if all principal minors are positive definite i.e., if
$\left(\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)}\right)<0,\left(\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial T^{2}}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)}\right)<0$
and
$\left|\begin{array}{ll}\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{1}^{*}, T_{1}^{*}\right)} & \left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\right|_{\left(t_{1}^{*}, T_{1}^{*}\right)} \\ \left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)} & \left(\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial T^{2}}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)}\right)\end{array}\right|>0$.
See the proof in Appendix 1c
(ii)If $\Delta_{1}<0$, then the total profit $T P_{1}\left(t_{1}, T\right)$ has a maximum value at the point $\left(t_{11}^{*}, T_{1}^{*}\right)$ where $t_{11}^{*}=t_{d}$ and $T_{1}^{*}=$ $\frac{1}{c_{b} \delta}\left(\mathrm{X}_{1} t_{d}-\mathrm{Y}_{1}\right)$
See the proof in Appendix 1d
For case $2\left(\boldsymbol{t}_{\boldsymbol{d}}<\boldsymbol{M} \leq \boldsymbol{t}_{1}\right)$
The necessary condition for the total profit $T P_{1}\left(t_{1}, T\right)$ in equation (39) to be the maximum are $\frac{\partial T P_{2}\left(t_{1}, T\right)}{\partial t_{1}}=0$ and $\frac{\partial T P_{2}\left(t_{1}, T\right)}{\partial T}=0$, which give
$\frac{\partial T P_{2}\left(t_{1}, T\right)}{\partial t_{1}}=\frac{d}{T}\left\{-X_{2} t_{1}+Y_{2}+C_{b} \delta T\right\}$
Setting $\frac{\partial T P_{2}\left(t_{1}, T\right)}{\partial t_{1}}=0$ gives
$\left\{-X_{2} t_{1}+Y_{2}+C_{b} \delta T\right\}=0$
and
$T=\frac{1}{C_{b} \delta}\left(X_{2} t_{1}-Y_{2}\right)$
Since $\left(t_{1}-t_{d}\right)>0,\left(t_{1}-M\right) \geq 0$, it should be noted that

$$
\begin{aligned}
\left(X_{2} t_{1}-Y_{2}=[ \right. & \left(C-S_{2}\right)(1-\delta)+h_{1}\left(t_{d} \theta\left(t_{1}-t_{d}\right)+t_{1}\right)+h_{2}\left(t_{1}-\frac{t_{d}}{2}\right) t_{d}+\frac{h_{2} t_{d} \theta}{2}\left(t_{1}-t_{d}\right) t_{d}+C \theta\left(t_{1}-t_{d}\right) \\
& \left.+C_{\pi}(\delta-1)+C_{b} \delta t_{1}+c I_{c}\left(t_{1}-M\right)\right]>0
\end{aligned}
$$

Provided

$$
\begin{gathered}
{\left[C+S_{2} \delta+h_{1}\left(t_{d} \theta\left(t_{1}-t_{d}\right)+t_{1}\right)+h_{2}\left(t_{1}-\frac{t_{d}}{2}\right) t_{d}+\frac{h_{2} t_{d} \theta}{2}\left(t_{1}-t_{d}\right) t_{d}+C \theta\left(t_{1}-t_{d}\right)+C_{\pi} \delta+C_{b} \delta t_{1}\right.} \\
\left.+c I_{c}\left(t_{1}-M\right)\right]>\left(S_{2}+C \delta+C_{\pi}\right)
\end{gathered}
$$

Similarly,
$\frac{\partial T P_{2}\left(t_{1}, T\right)}{\partial T}=-\frac{d}{T^{2}}\left\{-\frac{1}{2} X_{2} t_{1}^{2}+Y_{2} t_{1}-W_{2}+\frac{C_{b} \delta T^{2}}{2}\right\}$
Setting $\frac{\partial T P_{2}\left(t_{1}, T\right)}{\partial T}=0$ to obtain
$-\frac{d}{T^{2}}\left\{-\frac{1}{2} X_{2} t_{1}^{2}+Y_{2} t_{1}-W_{2}+\frac{C_{b} \delta T^{2}}{2}\right\}=0$
Substituting $T$ from equation (41) into equation (43) yields

$$
\begin{equation*}
\left\{X_{2}\left(C_{b} \delta-X_{2}\right) t_{1}^{2}-2 Y_{2}\left(C_{b} \delta-X_{2}\right) t_{1}-\left(Y_{2}^{2}-2 C_{b} \delta W_{2}\right)\right\}=0 \tag{44}
\end{equation*}
$$

Let $\Delta_{2}=X_{2}\left(C_{b} \delta-X_{2}\right) M^{2}-2 Y_{2}\left(C_{b} \delta-X_{2}\right) M\left(Y_{2}^{2}-2 C_{b} \delta W_{2}\right)$, then the following result is obtained.

## Lemma 2

(i) If $\Delta_{2} \geq 0$, then the solution of $t_{1} \in[M, \infty)$ (say $t_{12}^{*}$ ) which satisfies equation (44) not only exists but also is unique. The proof is similar to Appendix 1a, hence is omitted
(ii) If $\Delta_{2}<0$, then the solution of $t_{1} \in[M, \infty)$ which satisfies equation (44) does not exist.

The proof is similar to Appendix 1b, hence is omitted
Therefore, the value of $t_{1}$ (denoted by $t_{12}^{*}$ ) can be found from equation (44) and is given by
$t_{12}^{*}=\frac{Y_{2}}{X_{2}}+\frac{1}{X_{2}} \sqrt{\frac{\left(2 X_{2} W_{2}-Y_{2}^{2}\right) C_{b} \delta}{\left(X_{2}-C_{b} \delta\right)}}$
Once the value of $t_{12}^{*}$ is obtained, then the value of $T$ (denoted by $T_{2}^{*}$ ) can be found from (41) and is given by
$T_{2}^{*}=\frac{1}{C_{b} \delta}\left(X_{2} t_{12}^{*}-Y_{2}\right)$
Equations (45) and (46) give the optimal values of $t_{12}^{*}$ and $T_{2}^{*}$ for the profit function in equation (30) only if $Y_{2}$ satisfies the inequality given in equation (47)
$2 X_{2} W_{2}>Y_{2}^{2}$
Theorem 2
(i) If $\Delta_{2} \geq 0$, then the total profit $T P_{2}\left(t_{1}, T\right)$ is concave and reaches its global maximum at the point $\left(t_{12}^{*}, T_{2}^{*}\right)$, where $\left(t_{12}^{*}, T_{2}^{*}\right)$ is the point which satisfies equations (44) and (40), if all principal minors are positive definite i.e., if
$\left(\left.\frac{\partial^{2} T P_{2}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{12}^{*}, T_{2}^{*}\right)}\right)<0,\left(\left.\frac{\partial^{2} T P_{2}\left(t_{1}, T\right)}{\partial T^{2}}\right|_{\left(t_{12}, T_{2}^{*}\right)}\right)<0$
and
$\left|\begin{array}{ll}\left.\frac{\partial^{2} T P_{2}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{12}^{*}, T_{2}^{*}\right)} & \left.\frac{\partial^{2} T P_{2}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\right|_{\left(t_{12}^{*}, T_{2}^{*}\right)} \\ \left.\frac{\partial^{2} T P_{2}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\right|_{\left(t_{12}^{*}, T_{2}^{*}\right)} & \left(\left.\frac{\partial^{2} T P_{2}\left(t_{1}, T\right)}{\partial T^{2}}\right|_{\left(t_{12}^{*}, T_{2}^{*}\right)}\right)\end{array}\right|>0$.
The proof is similar to Appendix 1c, hence is omitted
(ii) If $\Delta_{2}<0$, then the total profit $T P_{2}\left(t_{1}, T\right)$ has a maximum value at the point $\left(t_{12}^{*}, T_{2}^{*}\right)$ where $t_{12}^{*}=t_{d}$ and $T_{2}^{*}=$ $\frac{1}{c_{b} \delta}\left(\mathrm{X}_{2} t_{d}-\mathrm{Y}_{2}\right)$
The proof is similar to Appendix 1d, hence is omitted

## For case $3 \quad\left(M>t_{1}\right)$

The necessary condition for the total profit $T P_{3}\left(t_{1}, T\right)$ in equation (40) to be the maximum are $\frac{\partial T P_{3}\left(t_{1}, T\right)}{\partial t_{1}}=0$ and $\frac{\partial T P_{3}\left(t_{1}, T\right)}{\partial T}=0$, which gives
$\frac{\partial T P_{3}\left(t_{1}, T\right)}{\partial t_{1}}=\frac{d}{T}\left\{-X_{3} t_{1}+Y_{3}+C_{b} \delta T\right\}$
Setting $\frac{\partial T P_{3}\left(t_{1}, T\right)}{\partial t_{1}}=0$ gives
$\left\{-X_{3} t_{1}+Y_{3}+C_{b} \delta T\right\}=0$
and
$T=\frac{1}{C_{b} \delta}\left(X_{3} t_{1}-Y_{3}\right)$
Since $\left(t_{1}-t_{d}\right)>0$, it should be noted that

$$
\begin{aligned}
\left(X_{3} t_{1}-Y_{3}\right)=[ & \left(C-S_{2}\right)(1-\delta)+h_{1}\left(t_{d} \theta\left(t_{1}-t_{d}\right)+t_{1}\right)+h_{2}\left(t_{1}-\frac{t_{d}}{2}\right) t_{d}+\frac{h_{2} t_{d} \theta}{2}\left(t_{1}-t_{d}\right) t_{d}+C \theta\left(t_{1}-t_{d}\right) \\
& \left.+C_{\pi}(\delta-1)+C_{b} \delta t_{1}+\frac{1}{d}\left\{S_{1} I_{e}\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)\right\}-S_{2} I_{e}\left(t_{d}+M\right)\right]>0
\end{aligned}
$$

Provided
$\left[C+S_{2} \delta+h_{1}\left(t_{d} \theta\left(t_{1}-t_{d}\right)+t_{1}\right)+h_{2}\left(t_{1}-\frac{t_{d}}{2}\right) t_{d}+\frac{h_{2} t_{d} \theta}{2}\left(t_{1}-t_{d}\right) t_{d}+C \theta\left(t_{1}-t_{d}\right)+C_{\pi} \delta+C_{b} \delta t_{1}\right.$

$$
\left.+\frac{1}{d}\left\{S_{1} I_{e}\left(a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}\right)\right\}\right]>\left(S_{2}+C \delta+C_{\pi}\right)+S_{2} I_{e}\left(t_{d}+M\right)
$$

Similarly,
$\frac{\partial T P_{3}\left(t_{1}, T\right)}{\partial T}=-\frac{d}{T^{2}}\left\{-\frac{1}{2} X_{3} t_{1}^{2}+Y_{3} t_{1}-W_{3}+\frac{C_{b} \delta T^{2}}{2}\right\}$
Setting $\frac{\partial T P_{3}\left(t_{1}, T\right)}{\partial T}=0$ to obtain
$-\frac{d}{T^{2}}\left\{-\frac{1}{2} X_{3} t_{1}^{2}+Y_{3} t_{1}-W_{3}+\frac{C_{b} \delta T^{2}}{2}\right\}=0$
Substituting $T$ from equation (49) into equation (51) yields

$$
\begin{equation*}
\left\{X_{3}\left(C_{b} \delta-X_{3}\right) t_{1}^{2}-2 Y_{3}\left(C_{b} \delta-X_{3}\right) t_{1}-\left(Y_{3}^{2}-2 C_{b} \delta W_{3}\right)\right\}=0 \tag{52}
\end{equation*}
$$

Let $\Delta_{3 a}=X_{3}\left(C_{b} \delta-X_{3}\right) t_{d}^{2}-2 Y_{3}\left(C_{b} \delta-X_{3}\right) t_{d}-\left(Y_{3}^{2}-2 C_{b} \delta W_{3}\right)$
and $\Delta_{3 b}=X_{3}\left(C_{b} \delta-X_{3}\right) M^{2}-2 Y_{3}\left(C_{b} \delta-X_{3}\right) M-\left(Y_{3}^{2}-2 C_{b} \delta W_{3}\right)$, then the following result is obtained.

## Lemma 3

(i) If $\Delta_{3 b} \leq 0 \leq \Delta_{3 a}$, then the solution of $t_{1} \in\left[t_{d}, M\right]$ (say $t_{13}^{*}$ ) which satisfies equation (52) not only exists but also is unique.
The proof is similar to Appendix 1a, hence is omitted.
(ii) If $\Delta_{3 a}<0$, then the solution of $t_{1} \in\left[t_{d}, M\right]$ which satisfies equation (52) does not exist.

The proof is similar to Appendix 1b, hence is omitted.
Therefore, the value of $t_{1}$ (denoted by $t_{13}^{*}$ ) can be found from equation (52) and is given by
$t_{13}^{*}=\frac{Y_{3}}{X_{3}}+\frac{1}{X_{3}} \sqrt{\frac{\left(2 X_{3} W_{3}-Y_{3}^{2}\right) C_{b} \delta}{\left(X_{3}-C_{b} \delta\right)}}$
Once the value of $t_{13}^{*}$ is obtained, then the value of $T$ (denoted by $T_{3}^{*}$ ) can be found from (49) and is given by
$T_{3}^{*}=\frac{1}{C_{b} \delta}\left(X_{3} t_{13}^{*}-Y_{3}\right)$
Equations (53) and (54) give the optimal values of $t_{13}^{*}$ and $T_{3}^{*}$ for the profit function in equation (31) only if $Y_{3}$ satisfies the inequality given in equation (55)
$2 X_{3} W_{3}>Y_{3}^{2}$

## Theorem 3

(i) If $\Delta_{3 a} \geq 0$, then the total profit $T P_{3}\left(t_{1}, T\right)$ is concave and reaches its global maximum at the point $\left(t_{13}^{*}, T_{3}^{*}\right)$, where $\left(t_{13}^{*}, T_{3}^{*}\right)$ is the point which satisfies equations (52) and (48), if all principal minors are positive definite i.e., if
$\left(\left.\frac{\partial^{2} T P_{3}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{13}^{*}, T_{3}^{*}\right)}\right)<0,\left(\left.\frac{\partial^{2} T P_{3}\left(t_{1}, T\right)}{\partial T^{2}}\right|_{\left(t_{13}, T_{3}^{*}\right)}\right)<0$
and
$\left.\left.\left|\begin{array}{ll}\left.\frac{\partial^{2} T P_{3}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{13}^{*}, T_{3}^{*}\right)} & \frac{\partial^{2} T P_{3}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\end{array}\right|_{\left(t_{13}^{*}, T_{3}^{*}\right)}\right|_{\left(t_{13}^{*}, T_{3}^{*}\right)}\left(\left.\frac{\partial^{2} T P_{3}\left(t_{1}, T\right)}{\partial T^{2}}\right|_{\left(t_{13}^{*}, T_{3}^{*}\right)}\right) \right\rvert\,>0$.
The proof is similar to Appendix 1c, hence is omitted
(ii) If $\Delta_{3 a}<0$, then the total profit $T P_{3}\left(t_{1}, T\right)$ has a maximum value at the point $\left(t_{13}^{*}, T_{3}^{*}\right)$ where $t_{13}^{*}=M$ and $T_{3}^{*}=\frac{1}{C_{b} \delta}\left(X_{3} M-Y_{3}\right)$.
The proof is similar to Appendix 1d, hence is omitted

UMYU Scientifica, Vol. 3 NO. 2, June 2024, Pp 016 - 035
(iii) If $\Delta_{3 b}>0$, then the total profit $T P_{3}\left(t_{1}, T\right)$ has a maximum value at the point $\left(t_{13}^{*}, T_{3}^{*}\right)$ where $t_{13}^{*}=t_{d}$ and $T_{3}^{*}=\frac{1}{C_{b} \delta}\left(X_{3} t_{d}-Y_{3}\right)$.
The proof is similar to Appendix 1d, hence is omitted
After obtaining the optimal values of $t_{1}^{*}$ and $T^{*}$, the optimal Economic Order Quantity (denoted by EOQ*) can be computed as follows:
$E O Q^{*}=$ Total demand before deterioration sets in + total demand after deterioration sets in + total number of deteriorated items + the total number of items back-ordered
$=a t_{d}+b \frac{t_{d}^{2}}{2}+c \frac{t_{d}^{3}}{3}+\frac{d}{\theta}\left(e^{\theta\left(t_{1}^{*}-t_{d}\right)}-1\right)+d \delta\left(T^{*}-t_{1}^{*}\right)$
Note: It is obvious when $t_{d}=t_{1}=M$ that $T P_{1}\left(t_{1}, T\right)=T P_{2}\left(t_{1}, T\right)=T P_{3}\left(t_{1}, T\right)$. When $t_{d}=M, T P_{1}\left(t_{1}, T\right)=$ $T P_{2}\left(t_{1}, T\right)$. When $t_{1}=M, T P_{2}(M, T)=T P_{3}(M, T)$. Hence, the profit function $T P\left(t_{1}, T\right)$ is continuous and welldefined.

## NUMERICAL RESULTS

## Example $6.1\left(\boldsymbol{M} \leq \boldsymbol{t}_{\boldsymbol{d}}\right)$

The following parameters are adopted from Babangida and Baraya (2021a) in addition to $h_{1}, \delta, C_{\pi}$ and $C_{b}$ which are not considered in their work. The parameters and their values are as follows:

Table 1: parameters and their values

| Parameter(s) | Value(s) |
| :---: | :---: |
| $A$ | $\$ 250 /$ order |
| $h_{1}$ | $\$ 2$ unit/year |
| $h_{2}$ | $\$ 15$ unit/year |
| $\theta$ | 0.01 unit/year |
| $a$ | 180 unit |
| $b$ | 30 unit |
| $c$ | 15 unit |
| $d$ | 120 unit |
| $t_{d}$ | 0.1354 year |
| $M$ | 0.0888 year |
| $I_{c}$ | 0.1 |
| $I_{e}$ | 0.08 |
| $C_{b}$ | $\$ 30$ |
| $\delta$ | 0.85 |
| $C_{\pi}$ | 1 |

It is seen that $M \leq t_{d}, \Delta_{1}=33.9202>0,2 X_{1} W_{1}=44.9517, Y_{1}^{2}=1.4200$ and $2 X_{1} W_{1}>Y_{1}^{2}$. Substituting the above values in equation (37), (47), (29) and (56), The result is obtained in the table below

Table 2: Optimal Solutions for case 1

| Parameters | Values |
| :---: | :--- |
| $t_{11}^{*}$ | 0.4863 (177 days) |
| $T_{1}^{*}$ | $0.5479(199$ days $)$ |
| $T P_{1}\left(t_{11}^{*}, T_{1}^{*}\right)$ | $\$ 303.2293$ |
| $E O Q_{1}^{*}$ | 73.1284 unit. |

## Example $6.2\left(M>t_{d}\right)$

The values of the parameters are same as in example 6.1 [as in Babangida and Baraya (2021)] except that $M=0.1523$. It is seen that $M>t_{d}, \Delta_{2}=32.7438>0,2 X_{2} W_{2}=44.3728, B_{2}^{2}=1.6559$ and $2 X_{2} W_{2}>Y_{2}^{2}$. Substituting the above values in equation (45), (46), (30) and (56). The result is obtained in the table below

Table 3: Optimal Solutions for case 2

| Parameters | Values |
| :---: | :---: |
| $t_{12}^{*}$ | 0.4851 (177 days) |
| $T_{2}^{*}$ | 0.5428 (198 days) |
| $T P_{2}\left(t_{12}^{*}, T_{2}^{*}\right)$ | $\$ 315.4550$ |
| $E O Q_{2}^{*}$ | 72.5857 unit. |

Example $6.3\left(M>t_{1}\right)$
The values of the parameters are same as in example 6.1 except that $M=0.36$. It is seen that $M>t_{d}, \Delta_{3 a}=16.2308>$ $0, \Delta_{3 b}=-0.1650<02 X_{3} W_{3}=23.9601, Y_{3}^{2}=2.0736$ and $2 X_{3} W_{3}>Y_{3}^{2}$. Substituting the above values in equation (53), (54), (31) and (56).The result is obtained in the table below.

Table 4: Optimal Solutions for case 3

| Parameters | Values |
| :---: | :---: |
| $t_{13}^{*}$ | $0.3585(130$ days $)$ |
| $T_{3}^{*}$ | $0.3834(139$ days $)$ |
| $T P_{3}\left(t_{13}^{*}, T_{3}^{*}\right)$ | $\$ 386.9494$ |
| $E O Q_{3}^{*}$ | 54.0035 unit. |

Table 5: Comparison table

| Comparison of our model with Babangida and Bature (2021a) |  |  |  |
| :---: | :---: | :---: | :---: |
| Models | Average total profit <br> per unit for case 1 | Average total profit per unit for case 2 | Average total <br> profit <br> per unit for case 3 |
| Babangida and Baraya (2021) | \$4.1341 | \$4.3176 | - |
| Proposed Model | \$4.1465 | \$4.3460 | \$7.1653 |

It is clearly seen from the table above that the average total profit for case 1 and case 2 of the proposed model is greater than that of Babangida and Baraya (2021). Hence the proposed model is more optimal than Babangida and Baraya (2021).

## SENSITIVITY ANALYSIS

The sensitivity analysis of some model parameters is performed by changing each of the parameters from $-6 \%,-3 \%,+6 \%$ to $+3 \%$ taking one parameter at a time and keeping the remaining parameters unchanged. The effects of these changes of parameters on cycle length, optimal time with positive inventory, total profit and economic order quantity per cycle are discussed and summarised in table 6,7 and 8 below:

UMYU Scientifica, Vol. 3 NO. 2, June 2024, Pp 016 - 035
Table 6: Effect of changes of some model parameters from $-6 \%,-3 \%,+3 \%$ to $+6 \%$ on decision variables for example 6.1

## RESULTS AND DISCUSSION

The following managerial insights are obtained based on the results shown in Tables 6, 7 and 8 .
(i)It is obviously seen that the higher the rate of deterioration $(\theta)$, the lower the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length ( $T^{*}$ ), order quantity $\left(E O Q^{*}\right)$ and the total profit $T P\left(T^{*}\right)$ and vice versa. This implies that the retailer needs to take all the necessary
measures to avoid or reduce deterioration to maximise higher profit.
(ii)It is visibly seen that as the unit purchasing cost $(C)$ increases, the total profit $T P\left(T^{*}\right)$ decreases while the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length $\left(T^{*}\right)$ and order quantity $\left(E O Q^{*}\right)$ increase and vice versa. This result reveals that when the unit purchasing cost increases, the retailer will order smaller quantity to enjoy the benefits of permissible delay in payments more
frequently, which will consequently shorten the cycle length.
(iii)It is apparently seen that as the unit selling price before deterioration sets in $\left(S_{1}\right)$ increases, the optimal time with positive inventory ( $t_{1}^{*}$ ), cycle length ( $T^{*}$ ) and order quantity $\left(E O Q^{*}\right)$ decrease while the total profit $T P\left(T^{*}\right)$ increases and vice versa. This implies that as the selling price increases the retailer will order less quantity to enjoy the benefits of trade credit more frequently.
(iv)It is evidently seen that as the unit selling price after deterioration sets in $\left(S_{2}\right)$ increases, the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length $\left(T^{*}\right)$, order quantity $\left(E O Q^{*}\right)$ and the total profit $T P\left(T^{*}\right)$ increase and vice versa. This implies that as the selling price increases, the retailer maximises higher profit.
(v) It is obviously seen that the lower the interest charged $\left(I_{c}\right)$ the higher the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length $\left(T^{*}\right)$, order quantity $\left(E O Q^{*}\right)$ and total profit $T P\left(T^{*}\right)$ and vice versa. This implies that when the interest charged is high the retailer is expected to order less quantity of inventory to enjoy the benefits of trade credit more frequently. As for case $3\left(M>t_{1}\right)$, any increase or decrease in the interest charged does not affect the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length $\left(T^{*}\right)$, order quantity $\left(E O Q^{*}\right)$ and total profit $T P\left(T^{*}\right)$, this is because the interest charged in this case is zero.
(vi)It is clearly seen that as the interest earned $\left(I_{e}\right)$ is increasing, the total profit $T P\left(T^{*}\right)$ is also increasing while the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length $\left(T^{*}\right)$ and order quantity $\left(E O Q^{*}\right)$ are decreasing and vice versa. This implies that when the interest earned is high the retailer should order less quantity of inventory to enjoy the benefits of trade credit more frequently.
(vii)It is obviously seen that as the ordering cost (A) is increasing the total profit $T P\left(T^{*}\right)$ is decreasing while the optimal time with positive inventory $\left(t_{1}^{*}\right)$, cycle length $\left(T^{*}\right)$ and order quantity $\left(E O Q^{*}\right)$ increase. This implies that the retailer should order large quantity when the ordering cost per order is high.
(viii)It is clearly seen that as the shortage cost $\left(C_{b}\right)$ increases the total profit $T P\left(T^{*}\right)$, the economic order quantity $\left(E O Q^{*}\right)$, the optimal cycle length $\left(T^{*}\right)$ decreases while the time with positive inventory increases.
(ix)It is evidently seen that as the unit cost of lost sales per unit $\left(C_{\pi}\right)$ increases the optimal time with positive inventory $\left(t_{1}^{*}\right)$ also increases while cycle length $\left(T^{*}\right)$, order quantity $\left(E O Q^{*}\right)$ and the total profit $T P\left(T^{*}\right)$ decrease.This implies that the retailer should order less quantity when the unit cost of lost sales is high.
(x)It is clearly seen that as the backlogging parameter is increasing, the cycle length $\left(T^{*}\right)$, order quantity $\left(E O Q^{*}\right)$ and the total profit $T P\left(T^{*}\right)$ are also increasing while the
optimal time with positive inventory $\left(t_{1}^{*}\right)$ is decreasing and vice versa. This implies that when the backlogging parameter is increasing, the retailer should order large quantity to get large profit.

## CONCLUSION

This research developed an economic order quantity model for non-instantaneous deteriorating items with two phase demand rates ,linear holding cost, complete backlogging rate and two-level pricing strategies under trade credit policy. The purpose of the model is to determine the optimal time with positive inventory, cycle length and order quantity such that the total profit of the inventory system has a maximum value. Some numerical examples have been given to illustrate the theoretical result of the model. Sensitivity analysis of some model parameters on the decision variables has been carried out and suggestions towards maximising the total profit were also given. The retailer can maximise the total profit by ordering less quantity and shorten the cycle length if the rate of deterioration, unit purchasing cost, interest charged, ordering cost, backlogging parameter and shortage cost increase and unit selling price before deterioration start, unit selling price after deterioration start interest earned and unit cost of lost sales per unit decrease. The model can be used in inventory control and management of items such as food items (e.g., beans, maise, corns, millet), electronics (e.g., mobile phones, computers), automobiles, fashionable items, etc. The proposed model can be extended by considering factors such as variable deterioration, inflation and time value of money, quantity discount, order size dependent trade credit, etc.

APPENDIX 1a:

## proof of lemma 1(i)

From equation (45), a new function $F_{1}\left(t_{1}\right)$ is defined as follows

$$
\begin{gather*}
F_{1}\left(t_{1}\right)=\left\{X_{1}\left(C_{b} \delta-X_{1}\right) t_{1}^{2}-2 Y_{1}\left(C_{b} \delta-X_{1}\right) t_{1}\left(Y_{1}^{2}-2 C_{b} \delta W_{1}\right)\right\}, \quad t_{1} \\
\in\left[t_{d}, \infty\right) \tag{66}
\end{gather*}
$$

Taking the first-order derivative of $F_{1}\left(t_{1}\right)$ with respect to $t_{1} \in\left[t_{d}, \infty\right)$, it follows that

$$
\begin{aligned}
\frac{F_{1}\left(t_{1}\right)}{d t_{1}} & =\left\{2 X_{1}\left(C_{b} \delta-X_{1}\right) t_{1}-2 Y_{1}\left(C_{b} \delta-X_{1}\right)\right\} \\
& =2\left(C_{b} \delta-X_{1}\right)\left(X_{1} t_{1}-Y_{1}\right)<0
\end{aligned}
$$

Because $\left(X_{1} t_{1}-Y_{1}\right)>0$
and

$$
\begin{aligned}
\left(C_{b} \delta-X_{1}\right)= & C_{b} \delta-\left[h_{1}\left(t_{d} \theta+1\right)+h_{2}\left(1+\frac{t_{d} \theta}{2}\right) t_{d}+C \theta+C_{b} \delta+c I_{c}\left(\theta\left(t_{d}-M\right)+1\right)\right] \\
& =-\left[h_{1}\left(t_{d} \theta+1\right)+h_{2}\left(1+\frac{t_{d} \theta}{2}\right) t_{d}+C \theta+c I_{c}\left(\theta\left(t_{d}-M\right)+1\right)\right]<0
\end{aligned}
$$

Hence $F_{1}\left(t_{1}\right)$ is a strictly decreasing function of $t_{1}$ in the interval $\left[t_{d}, \infty\right)$. Moreover, $\lim _{t_{1} \rightarrow \infty} F_{1}\left(t_{1}\right)=-\infty$ and $F_{1}\left(t_{d}\right)=\Delta_{1} \geq 0$. Therefore, by applying intermediate value theorem, there exists a unique $t_{1}$ say $t_{11}^{*} \in\left[t_{d}, \infty\right)$ such that $F_{1}\left(t_{11}^{*}\right)=0$. Hence $t_{11}^{*}$ is the unique solution of equation (45).

## APPENDIX 1b:

proof of lemma 1(ii)
If $\Delta_{1}<0$, then from equation (46), $F_{1}\left(t_{1}\right)<0$. Since $F_{1}\left(t_{1}\right)$ is a strictly decreasing function of $t_{1} \in\left[t_{d}, \infty\right)$ and $F_{1}\left(t_{1}\right)<0$ for all $T \in\left[t_{d}, \infty\right)$. Therefore, a value of $T \in\left[t_{d}, \infty\right)$ such that $F_{1}\left(t_{1}\right)=0$ cannot found. This completes the proof.
APPENDIX 1c: proof of Theorem 1(i)
When $\Delta_{1} \geq 0$, it is seen that $t_{11}^{*}$ and $T_{1}^{*}$ are the unique solutions of equations (44) and (40) respectively from Lemma l(i). Taking the second derivative of $T P_{1}\left(t_{1}, T\right)$ with respect to $t_{1}$ and $T$, and then finding the values of these functions at the point $\left(t_{11}^{*}, T_{1}^{*}\right)$, it follows that

$$
\begin{aligned}
\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)} & =-\frac{d}{T_{1}^{*}} \mathrm{X}_{1}<0 \\
\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)}= & -\frac{d}{T_{1}^{* 2}}\left\{-\mathrm{X}_{1} t_{11}^{*}+\mathrm{Y}_{1}+C_{b} \delta T_{1}^{*}\right\}+\frac{d}{T_{1}^{*}}\left\{C_{b} \delta\right\} \\
& =\frac{d}{T_{1}^{*}} C_{b} \delta \\
= & \frac{2 d}{T_{1}^{* 3}}\left\{-\frac{1}{2} \mathrm{X}_{1} t_{11}^{* 2}+\mathrm{Y}_{1} t_{11}^{*}-\mathrm{W}_{1}+\frac{C_{b} \delta T_{1}^{* 2}}{2}\right\}-\frac{d}{T_{1}^{* 2}}\left\{C_{b} \delta T_{1}^{*}\right\} \\
& =-\frac{d}{T_{1}^{*}} C_{b} \delta<0
\end{aligned}
$$

and

$$
\begin{aligned}
&\left(\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1}^{2}}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)}\right)\left(\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial T^{2}}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)}\right)-\left(\left.\frac{\partial^{2} T P_{1}\left(t_{1}, T\right)}{\partial t_{1} \partial T}\right|_{\left(t_{11}^{*}, T_{1}^{*}\right)}\right)^{2} \\
&=\left(-\frac{d}{T_{1}^{*}} \mathrm{X}_{1}\right)\left(-\frac{d}{T_{1}^{*}} C_{b} \delta\right)-\left(\frac{d}{T_{1}^{*}} C_{b} \delta\right)^{2} \\
&=\frac{d^{2}}{T_{1}^{* 2}} \mathrm{X}_{1} C_{b} \delta-\frac{d^{2}}{T_{1}^{* 2}} C_{b}^{2} \delta^{2}
\end{aligned}
$$

$$
\begin{align*}
& =\frac{d^{2} C_{b} \delta}{T_{1}^{* 2}}\left(\mathrm{X}_{1}-C_{b} \delta\right) \\
& =\frac{d^{2} C_{b} \delta}{T_{1}^{* 2}}\left(\left[h_{1}\left(t_{d} \theta+1\right)+h_{2}\left(1+\frac{t_{d} \theta}{2}\right) t_{d}+C \theta+C_{b} \delta+c I_{c}\left(\theta\left(t_{d}-M\right)+1\right)\right]-C_{b} \delta\right) \\
= & \frac{d^{2} C_{b}}{T_{1}^{* 2}}\left(\left[h_{1}\left(t_{d} \theta+1\right)+h_{2}\left(1+\frac{t_{d} \theta}{2}\right) t_{d}+C \theta+c I_{c}\left(\theta\left(t_{d}-M\right)+1\right)\right]\right) \\
> & 0 \tag{67}
\end{align*}
$$

It is therefore conclude from (48) and Lemma 1 that $T P_{1}\left(t_{11}^{*}, T_{1}^{*}\right)$ is concave and $\left(t_{11}^{*}, T_{1}^{*}\right)$ is the global maximum point of $T P_{1}\left(t_{1}, T\right)$. Hence the values of $t_{1}$ and $T$ in (45) and (46) are optimal.

## APPENDIX 1d:

## proof of Theorem 1(ii)

When $\Delta_{1}<0$, then $F_{1}\left(t_{1}\right)<0$ for all $t_{1} \in\left[t_{d}, \infty\right)$. Therefore, $\frac{\partial T P_{1}\left(t_{1}, T\right)}{\partial T}=\frac{F_{1}\left(t_{1}\right)}{T^{2}}<0$ for all $t_{1} \in\left[t_{d}, \infty\right)$ which implies $T P_{1}\left(t_{1}, T\right)$ is a strictly decreasing function of $t_{1}$. Therefore, $T P_{1}\left(t_{1}, T\right)$ has a maximum value when $t_{1}$ is minimum. Therefore, $T P_{1}\left(t_{1}, T\right)$ has a maximum value at the point $\left(t_{11}^{*}, T_{1}^{*}\right)$ where $t_{11}^{*}=t_{d}$ and $T_{1}^{*}=$ $\frac{1}{c_{b} \delta}\left(\mathrm{X}_{1} t_{d}-\mathrm{Y}_{1}\right)$. This completes the proof.
